2-1 The Nature of Matter ➡ Atoms

### Atoms

The study of chemistry begins with the basic unit of matter, the **atom**.

The Greek philosopher Democritus called the smallest fragment of matter the atom, from the Greek word *atomos*.

Slide 3 of 40

---

---

---

---

---

---

---

---

Placed side by side, 100 million atoms would make a row only about 1 centimeter long.

Atoms contain subatomic particles that are even smaller.

---

---

---

---

---

---

---

---

**What three subatomic particles make up atoms?**

---

---

---

---

---

---

---

---

**The subatomic particles that make up atoms are**

- protons
- neutrons
- electrons

---

2-1 The Nature of Matter ➡ Atoms

Protons and neutrons have about the same mass.

Protons are positively charged particles (+).

Neutrons carry no charge.

Strong forces bind protons and neutrons together to form the **nucleus**, which is at the center of the atom.

2-1 The Nature of Matter ➡ Atoms

The **electron** is a negatively charged particle (-) with 1/1840 the mass of a proton.

Electrons are in constant motion in the space surrounding the nucleus.

PEARSON Prentice Hall

Slide 9 of 40

---

---

---

---

---

---

---

---

Electrons are attracted to the positively charged nucleus but remain outside the nucleus because of the energy of their motion.

---

---

---

---

---

---

---

---

Because atoms have equal numbers of electrons and protons, and because these subatomic particles have equal but opposite charges, atoms are neutral.

---

---

---

---

---

---

---

---

## Elements and Isotopes

A chemical **element** is a pure substance that consists entirely of one type of atom.

Elements are represented by a one- or two-letter symbol.

- C stands for carbon.
- Na stands for sodium.

---

---

---

---

---

---

---

---

2-1 The Nature of Matter ➡ Elements and Isotopes

The number of protons in an atom of an element is the element's atomic number.

Carbon has 6 protons, so its atomic number is 6.

More than 100 elements are known, but only about two dozen are commonly found in living organisms.

2-1 The Nature of Matter ➡ Elements and Isotopes

**Isotopes**

Atoms of the same element that differ in the number of neutrons they contain are known as **isotopes**.

The sum of the protons and neutrons in the nucleus of an atom is called its mass number.

---

---

2-1 The Nature of Matter ➡ Elements and Isotopes

Isotopes are identified by their mass numbers.

For example, carbon has three isotopes—carbon-12, carbon-13, and carbon-14. Each isotope has a different number of neutrons.

### Radioactive Isotopes

Some isotopes are radioactive, meaning that their nuclei are unstable and break down at a constant rate over time.

Although the radiation these isotopes give off can be dangerous, they have important scientific and practical uses.

---

---

---

---

---

---

---

---

Radioactive isotopes can be used:

- to determine the ages of rocks and fossils.
- to treat cancer.
- to kill bacteria that cause food to spoil.
- as labels or “tracers” to follow the movement of substances within an organism.

---

---

---

---

---

---

---

---

### Chemical Compounds

In nature, most elements are found combined with other elements in compounds.

A chemical **compound** is a substance formed by the chemical combination of two or more elements in definite proportions.

The physical and chemical properties of a compound are different from the elements from which it is formed.

---

---

---

---

---

---

---

---

Scientists show the composition of compounds by a kind of shorthand known as a chemical formula.

Water,  $\text{H}_2\text{O}$ , contains two atoms of hydrogen for each atom of oxygen.

The formula for table salt,  $\text{NaCl}$ , indicates that sodium and chlorine combine in a 1 : 1 ratio.

---

---

---

---

---

---

---

---

**What are the two main types of chemical bonds?**

---

---

---

---

---

---

---

---

## Chemical Bonds

The atoms in compounds are held together by **chemical bonds**.

Bond formation involves the electrons that surround each atomic nucleus.

The electrons that are available to form bonds are called valence electrons.

---

---

---

---

---

---

---

---

2-1 The Nature of Matter ➡ Chemical Bonds

 The main types of chemical bonds are:

- ionic bonds
- covalent bonds

---

---

---

---

2-1 The Nature of Matter ➡ Chemical Bonds

**Ionic Bonds**

An **ionic bond** is formed when one or more electrons are transferred from one atom to another.

An atom that loses electrons has a positive charge.

An atom that gains electrons has a negative charge.

These positively and negatively charged atoms are known as **ions**.

### Covalent Bonds

Sometimes electrons are shared by atoms instead of being transferred.

Sharing electrons means that the moving electrons actually travel in the orbitals of both atoms.

---

---

---

---

---

---

---

---

A **covalent bond** forms when electrons are shared between atoms.

- When the atoms share two electrons, the bond is called a single covalent bond.
- When atoms share four electrons it is called a double bond.
- When atoms share six electrons it is called a triple bond.

---

---

---

---

---

---

---

---

The structure that results when atoms are joined together by covalent bonds is called a **molecule**.

A molecule is the smallest unit of most compounds.

---

---

---

---

---

---

---

---

In a water molecule, each hydrogen atom forms a single covalent bond with the oxygen atom.

Water Molecule

---

---

---

---

---

---

---

---

### Van der Waals Forces

When molecules are close together, a slight attraction can develop between the oppositely charged regions of nearby molecules.

Chemists call such intermolecular forces of attraction **van der Waals forces**, after the scientist who discovered them.

---

---

---

---

---

---

---

---

Although van der Waals forces are not as strong as ionic bonds or covalent bonds, they can hold molecules together, especially when the molecules are large.

---

---

---

---

---

---

---

---

For example, van der Waals forces form between the molecules on the surface of a gecko's foot and the molecules on the surface of the wall.

The combined strength of all the van der Waals forces allows the gecko to grip the wall.

---

---

---

---

---

---

---

---
