

4-4 Aquatic Ecosystems

Nearly three-fourths of the Earth's surface is covered with water.

Almost all bodies of water contain a wide variety of communities governed by biotic and abiotic factors including light, nutrient availability, and oxygen.

4-4 Aquatic Ecosystems

Aquatic ecosystems are often grouped according to the abiotic factors that affect them.

The depth of water determines the amount of light that organisms receive.

4-4 Aquatic Ecosystems

Water chemistry refers to the amount of dissolved chemicals on which life depends.

Communities of organisms found in shallow water close to shore can be very different from the communities that occur away from shore in deep water.

Latitude is an important abiotic factor to both land biomes and aquatic ecosystems.

4-4 Aquatic Ecosystems - Freshwater Ecosystems

Flowing-Water Ecosystems

Rivers, streams, creeks, and brooks are freshwater ecosystems that flow over land.

Organisms that live there are well adapted to the rate of flow.

4-4 Aquatic Ecosystems Freshwater Ecosystems

Flowing-water ecosystems originate in mountains or hills.

Turbulent water near the source has little plant life.

As the water flows downhill, sediments build up and enable plants to grow.

Downstream, water may meander slowly, where turtles, beavers, and river otters live.

4-4 Aquatic Ecosystems - Freshwater Ecosystems

Standing-Water Ecosystems

Lakes and ponds are standing-water ecosystems.

In addition to the net flow of water in and out of these systems, there is usually water circulating within them.

This circulation helps to distribute heat, oxygen, and nutrients throughout the ecosystem.

4-4 Aquatic Ecosystems reshwater Ecosystems

Still waters provide habitats for organisms such as plankton.

Plankton is a general term for free-floating organisms that live in both freshwater and saltwater environments.

4-4 Aquatic Ecosystems 🔿 Freshwater Ecosystems

Unicellular algae, or **phytoplankton**, are supported by nutrients in the water and form the base of many aquatic food webs.

Zooplankton are unicellular animals that feed on phytoplankton.

4-4 Aquatic Ecosystems - Freshwater Ecosystems

Freshwater Wetlands

A **wetland** is an ecosystem in which water covers the soil or is present at or near the surface of the soil at least part of the year.

The water in wetlands may be flowing or standing and fresh, salty, or brackish.

Many wetlands are productive ecosystems that serve as breeding grounds for many types of wildlife.

The three main types of freshwater wetlands are bogs, marshes, and swamps.

Bogs are wetlands that typically form in depressions where water collects.

Marshes are shallow wetlands along rivers.

In swamps, which often look like flooded forests, water flows slowly.

Estuaries

Estuaries are wetlands formed where rivers meet the sea.

Estuaries contain a mixture of fresh and salt water, and are affected by the ocean tides.

4-4 Aquatic Ecosystems 🛶 Estuaries

Primary producers include plants, algae, and bacteria.

In estuary food webs, most primary production is not consumed by herbivores. Instead, much of that organic material enters the food web as detritus.

Detritus is made up of tiny pieces of organic material that provide food for organisms at the base of the estuary's food web.

4-4 Aquatic Ecosystems 🕩 Estuaries

Salt marshes are temperate-zone estuaries dominated by salt-tolerant grasses above the low-tide line, and by seagrasses under water.

Salt marshes occur in estuaries along seacoasts in the temperate zone.

4-4 Aquatic Ecosystems 🛶 Estuaries

Mangrove swamps are coastal wetlands that occur in bays and estuaries across tropical regions, including southern Florida and Hawaii.

The dominant plants are salt-tolerant trees, called mangroves, with seagrasses common below the low-tide line.

4-4 Aquatic Ecosystems 🕩 Marine Ecosystems

Marine Ecosystems

The well-lit upper layer of the ocean is known as the **photic zone**.

Algae and other producers can grow only in this thin surface layer.

4-4 Aquatic Ecosystems → Marine Ecosystems

Chemosynthetic autotrophs are the only producers that can survive in the aphotic zone.

4-4 Aquatic Ecosystems 🛶 Marine Ecosystems

Intertidal Zone

Organisms that live in the intertidal zone are exposed to regular and extreme changes in their surroundings.

Competition among organisms in the rocky intertidal zone often leads to **zonation**, the prominent arrangement of organisms in a particular habitat in horizontal bands.

4-4 Aquatic Ecosystems Marine Ecosystems

Coastal Ocean

The **coastal ocean** extends from the low-tide mark to the outer edge of the continental shelf.

It falls within the photic zone, and photosynthesis occurs throughout its depth.

The coastal ocean is often rich in plankton and many other organisms.

Kelp forests are named for their dominant organism, a giant brown alga. Kelp forests are one of the most productive coastal ocean communities.

Kelp forests support a complex food web.

4-4 Aquatic Ecosystems → Marine Ecosystems

Coral Reefs

Coral reefs, found in tropical coastal waters, are named for the coral animals whose calcium carbonate skeletons make up their primary structure.

An extraordinary diversity of organisms flourishes among coral reefs.

Reef-building corals grow with the help of algae that live symbiotically within their tissues.

4-4 Aquatic Ecosystems 🔿 Marine Ecosystems

Open Ocean

The open ocean, the oceanic zone, extends from the edge of the continental shelf outward.

It is the largest marine zone.

Most of the photosynthetic activity on Earth occurs in the photic zone of the open ocean by the smallest producers.

4-4 Aquatic Ecosystems 🔿 Marine Ecosystems

Fishes of all shapes and sizes dominate the open ocean.

Marine mammals live there but must stay close to the surface to breathe.

4-4 Aquatic Ecosystems 🛶 Marine Ecosystems

Benthic Zone

The ocean floor contains organisms that live attached to or near the bottom.

These organisms are called **benthos**. The ocean floor is called the benthic zone.

4-4 Aquatic Ecosystems Marine Ecosystems

This zone extends horizontally along the ocean floor from the coastal ocean through the open ocean.

Benthic ecosystems often depend on food from organisms that grow in the photic zone.

Chemosynthetic primary producers support life without light near deep-sea vents.

Section QUIZ	0.	QuickTake
PEARSON		Slide 34 of 35
Prentice Hall	Copyright Pearson Prentice F	ai la

4-4 Section QUIZ

- Which of the following factors is important in determining the type of aquatic ecosystem found in a specific area?
 - a. geographic location
- A b. amount of dissolved chemicals
 - c. the percentage of land covered by water
 - d. the kinds of organisms in the water

4-4 Section QUIZ

- 2 The two types of freshwater ecosystems are distinguished by whether or not they have
 - a. high oxygen content or low oxygen content.
 - b. phytoplankton or zooplankton.
 - c. high temperature or low temperature.
- A d. flowing water or standing water.

4-4 Section QUIZ

- 4 Coral animals cannot grow in water that
 - a. contains salt.
 - b. contains oxygen.
- A c. is cold.d. receives sunlight.

4-4 Section QUIZ

5 The zone that covers the ocean floor is the
A a. benthic zone.
b. abyssal plain.
c. continental shelf.
d. continental rise.
